PROJECT PROPOSAL REPORT

SellerOS

AI-Powered Business Intelligence and Decision Support
for Social-Commerce Sellers

Software Engineering Capstone Project

Course: SE-331

Prepared by:

Monira Islam (232-35-017)

Rukaiya Akther Trisha (232-35-292)

Instructor:

Farhan Tanvir, Lecturer, Department of Software Engineering (SWE), DIU

Date: 03-10-2026

1. Introduction

SellerOS is a proposed web application for small and medium-sized social-commerce sellers who manage products and customer orders mainly through social-media channels. Its central purpose is to turn the business records that sellers maintain into understandable analysis and practical decision support. Product, stock, order, customer, and cost records provide the data foundation; AI and machine-learning components use that data to assist with customer replies, business insights, customer grouping, demand estimation, profitability analysis, and scenario exploration. The first capstone version will be a standalone application and will not depend on live integrations with social-media, courier, or payment platforms.

1.1 Background Overview

Social-commerce sellers often receive enquiries and orders through more than one communication channel. They may record products, stock, customer details, delivery costs, and order status in separate tools or in informal records. When information is fragmented, sellers must manually combine it to answer routine questions, understand which products perform well, estimate replenishment needs, or determine whether sales are profitable after costs. The project treats these as practical information-management and decision-support needs rather than assuming that all sellers use the same workflow.

Business software commonly provides structured product, inventory, order, customer, and reporting functions. AI capabilities are also appearing in commerce products. For example, Shopify documents AI-generated product-description suggestions and an AI-enabled assistant that can provide guidance and help with reports or business tasks [1–3]. These examples show that AI can support content work and access to business information. They do not establish that every seller platform offers the same functions, nor do they demonstrate that a general-purpose assistant can provide reliable, seller-specific forecasts or profit estimates without suitable business data.

SellerOS proposes to connect basic operational records with a focused analysis layer. This is relevant to sellers whose information is not already available in one system and who need help interpreting their own sales and customer records. The proposal does not assume that social-platform data can be collected automatically. During the prototype, data will be entered or imported through the application, and the team will evaluate the features using suitable project or test data.

1.2 Problem Statement

Small social-commerce sellers may manage products, stock, orders, customer histories, and expenses across separate tools. This can require repeated manual work and make it difficult to form a consistent view of business performance. Sales totals alone do not show estimated profit when product cost, delivery cost, discounts, and other recorded expenses are relevant. Sellers may also need to review order histories manually to identify repeat or inactive customers, and past sales may be difficult to interpret when deciding how much stock to prepare.

Existing management functions can store and display records, but storage and standard charts alone do not explain what the records may mean or help sellers explore a decision. A business owner may have to compare figures manually, draft replies by looking up product information, or estimate the effect of a price change without a structured method. The proposed capstone addresses this gap by combining seller-entered business data with AI-assisted interpretation and limited machine-learning analysis.

The project will not claim to eliminate business uncertainty. Forecasts and scenario outputs depend on the quality and amount of data available, and AI-generated text may be incomplete or incorrect. The system must show the data and assumptions behind its outputs where feasible, and sellers will remain responsible for checking suggestions before acting on them.

1.3 Objectives

General Objective

To design and implement a standalone web-based business intelligence and decision-support platform that helps social-commerce sellers organize their business records and use those records to understand performance and explore routine business decisions.

AI Objective

To develop and evaluate AI/ML functions for grounded customer-reply suggestions, business insights, behavior-based customer segmentation, and demand forecasting, alongside AI-supported interpretation of business and financial metrics and clearly labeled what-if estimates; financial calculations will remain deterministic.

Specific objectives are to:

- provide connected product, inventory, order, customer, and expense records for a seller account;
- calculate sales and estimated profit using the cost fields entered by the seller;
- generate customer-reply suggestions grounded in the seller's product, price, and stock records;
- summarize relevant performance patterns in plain language using the seller's available data;
- group customers using defined purchase-behavior features without using sensitive personal attributes;
- estimate future product demand when sufficient historical sales data is available;
- let a seller explore price or discount scenarios and review the assumptions behind the resulting estimate;
- test the system's main workflows and assess AI outputs with documented criteria and representative test cases.

1.4 Scope

In-Scope

- Seller/store account and business profile management for the prototype.
- Product catalogue records, including product name, category, price, cost, variants, and available stock.
- Inventory quantity updates and low-stock indicators based on seller-defined values.
- Order creation and tracking through a defined set of statuses; order data will connect to customers and products.
- Customer profiles and purchase history derived from orders entered in SellerOS.
- Sales dashboards and estimated-profit calculations from recorded revenue, product cost, delivery cost, discounts, and other entered expenses.
- An internal AI inbox where a seller can enter or paste a customer message and receive a suggested reply.
- AI-generated business summaries based on the seller's available records.
- Behavior-based customer segments such as new, repeat, high-value, or inactive, based on documented rules or suitable analysis.
- Product-level demand forecasts where the amount and quality of historical data support forecasting.
- A what-if interface for selected price or discount changes, with output presented as an estimate and with assumptions disclosed.
- Testing, evaluation, and a capstone demonstration using project, sample, or otherwise authorized data.

Out-of-Scope

- Live Facebook Messenger, Instagram, or WhatsApp Business API integration in the initial prototype.
- Automatic sending of AI-generated replies or automated customer follow-up without seller review.
- Courier booking or tracking APIs, payment-gateway processing, and financial-accounting integration.
- A guarantee of forecast accuracy, sales growth, or improved business outcomes.
- Credit scoring, sensitive personal profiling, or decisions about customers that affect access to products or services.
- A general autonomous AI agent that can make purchases, change prices, contact customers, or alter inventory without approval.
- Complex multi-store enterprise operations, tax advice, or formal accounting statements.

AI responsibilities and boundaries

The AI/ML components will analyze available seller-entered records, identify patterns within supported data, estimate demand or selected scenarios, and produce text suggestions that help a seller interpret the results. The AI customer assistant will retrieve relevant catalogue and stock facts from the current store records before drafting a reply. Business summaries will be based on computed metrics and retrieved records rather than invented business facts.

The AI will not independently send messages, change product prices, place orders, make financial commitments, guarantee a future result, or infer sensitive traits. When a model cannot produce a meaningful estimate because the history is too limited or incomplete, the system should explain that limitation and present available descriptive information instead of implying certainty. The prototype boundary is one standalone SellerOS application using data entered or imported by an authorized user.

1.5 Stakeholders

Stakeholder	Role and interest
Social-commerce seller / store owner	Primary user. Maintains business records, reviews insights and forecasts, and decides whether to act on AI suggestions.
Seller staff or authorized user	May enter products, orders, and customer information, and use the internal AI inbox within the permissions assigned by the owner.
System administrator	Maintains application availability, manages technical configuration, and supports user access and troubleshooting.
Project team	Analyzes requirements, builds and integrates the prototype, protects test data, and jointly validates the application and AI components.

Stakeholder	Role and interest
Instructor / evaluator	Reviews the project's feasibility, alignment with software-engineering objectives, implementation, and evaluation evidence.

1.6 Proposed Solution

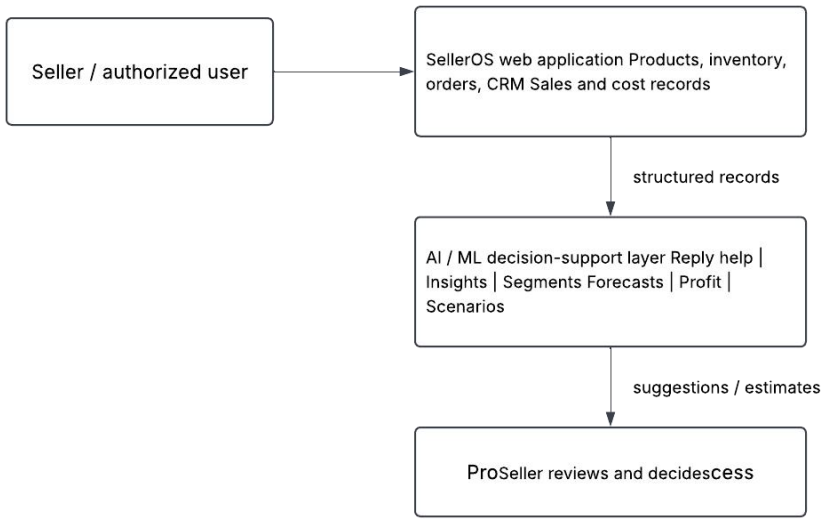

SellerOS will provide one workspace for a seller's operational records and a set of AI/ML functions that interpret those records. A seller first creates a store profile and records products, costs, stock, customers, and orders. The application updates linked inventory and customer histories and calculates descriptive sales and estimated-profit measures. AI/ML services then use selected records to provide a grounded reply suggestion, a business summary, a customer segment, a demand estimate, or a scenario estimate. The seller reviews the result and remains responsible for the business decision.

The product and order modules are supporting functions: they create the structured data the analysis needs. The central project value is the analysis and decision-support layer that uses this data to help sellers interpret business conditions. This separation avoids describing ordinary record creation as AI functionality.

Main workflow

- The seller creates a store profile and adds products, stock levels, prices, and costs.
- The seller records orders and links them to customers and products; inventory and customer histories are updated from those records.
- The analytics layer calculates sales and estimated profitability from the fields available for each transaction.
- The seller selects an AI task, such as drafting a reply, reviewing a trend, viewing a customer group, forecasting demand, or testing a scenario.
- The system checks data availability, performs the relevant retrieval or analysis, and returns an output with its basis or limitations.
- The seller reviews the output and chooses whether to use it.

Figure 1. SellerOS system overview

1.7 AI Features

Existing AI Features

AI in commerce software can support content generation and help users work with business information. Shopify's documentation describes Shopify Magic as generating suggested product descriptions from seller-provided details, while Sidekick is described as an AI-enabled commerce assistant that can provide guidance and help with tasks and reports [1–3]. These examples are evidence of capabilities in one established commerce platform, not a complete survey of tools used by social-commerce sellers.

Such features may be tied to a specific platform's data model and account environment. A seller who records orders and costs outside that platform may still need to assemble data manually. Generated text also requires review, and an assistant's output is only as useful as the context and records available to it. SellerOS will therefore focus on its own recorded product, customer, order, and cost data. It will not claim that no comparable tool exists or that its proposed functions outperform other systems. A broader comparison would require a separately scoped literature and product review.

Proposed AI Features

Feature	Input and processing	Output, reduced manual work, and seller benefit
AI Customer Assistant	A seller-entered customer message plus relevant product, variant, price, and stock records. The system identifies the likely question and retrieves matching store facts; an LLM drafts a response from that context.	A reply suggestion for the seller to review and edit. Reduces repeated catalogue lookups and routine drafting. The seller remains responsible for sending an accurate response.
AI Business Advisor	Selected sales, order, inventory, customer, and cost summaries. The application computes descriptive metrics and gives those results to an LLM to explain in plain language.	A concise insight summary with the metric or records it refers to. Reduces manual comparison of figures and helps the seller notice trends or issues.
Customer Segmentation	Order count, recency, spending, and product/category purchase history available in the store. Rule-based thresholds or an appropriate unsupervised method may be used and documented.	Labels such as new, repeat, high-value, or inactive, with the criteria shown. Reduces manual sorting of customer histories and supports more organized follow-up planning.
Demand Forecasting	Time-ordered product sales history and relevant stock/sales information. A baseline time-series or regression approach will be selected after inspecting data sufficiency; model results will be compared with a simple baseline.	An estimated quantity for a stated future period, with the period and data limitations shown. Supports stock planning and reduces reliance on unaided guesswork.
Profit Intelligence	Recorded revenue, product cost, delivery cost, discounts, and other available expenses. Deterministic calculations produce estimated profit and margins; AI may explain the calculation in plain language.	Estimated profit by order, product, or period, plus an explanation of included fields. Reduces manual arithmetic and helps distinguish sales revenue from estimated profit.
What-if Business Simulator	A selected product and a proposed price or discount change, along with relevant historical sales and cost data. The application applies a documented scenario method; any model-based relationship is used only when data supports it.	A clearly labeled estimate of possible sales, revenue, or profit changes and the assumptions used. Helps the seller compare scenarios without presenting the estimate as a guaranteed outcome.

AI Techniques

- Large language model (LLM) integration for drafting customer replies and explaining computed business summaries. The LLM receives only the context needed for the requested task.
- Grounding through retrieval from the seller's own structured catalogue and store records. For customer replies, retrieved product, price, variant, and stock values constrain the response; external knowledge is not needed for these store-specific facts.
- Structured data analysis with Python, Pandas, and NumPy to clean, aggregate, and prepare order, customer, and inventory features.
- Supervised forecasting or a simpler statistical/baseline method for product demand, chosen after inspecting available history. XGBoost will be considered only if it is suitable for the data and can be compared fairly with a baseline.
- Rule-based customer segments for interpretable initial categories; an unsupervised clustering method may be evaluated if it adds value and can be explained to users.
- Deterministic formulas for profit calculations and transparent scenario logic. Machine learning will not be used where a direct calculation is more appropriate.

The team will validate AI features jointly using documented test cases and the available authorized data. Customer-reply suggestions will be assessed for relevance, factual consistency with retrieved store records, groundedness, and unsupported content. Business insights will be checked against the computed metrics and reviewed for usefulness; segment criteria will be checked for consistency and interpretability; forecasts will be compared with a simple baseline using time-aware validation where sufficient history exists; and profit arithmetic and scenario results will be checked against their explicit inputs and formulas. These are planned evaluation activities, not completed results. No accuracy threshold or business impact is assumed in this proposal.

Why AI Is Essential

SellerOS is intended to help sellers interpret records and explore decisions, not only to store them. Without AI/ML analysis, the application could still maintain products and orders, but it would not fulfill its stated main purpose of turning business data into grounded summaries, demand estimates, behavior-based groupings, and assisted replies. The management modules provide necessary inputs; the AI/ML and analytical layer provides the decision-support value.

The intended relationship is: SellerOS = seller business data + AI/ML analysis + intelligent decision support. A chatbot alone would not meet this goal. The system must connect each generated answer to relevant store data, use explicit calculations or models for numerical results, and identify when the evidence is insufficient.

2. System Requirements

The following requirements describe the minimum expected behavior of the capstone prototype. Requirements that depend on AI outputs will be tested using defined test records and documented evaluation criteria. Model accuracy and response times will be measured during implementation rather than assumed here.

Functional Requirements

ID	Requirement
FR-01	The system shall allow an authorized user to create and update a seller/store profile.

ID	Requirement
FR-02	The system shall allow an authorized user to add, view, update, and deactivate product records, including name, category, price, cost, variants, and stock quantity.
FR-03	The system shall allow a user to record inventory changes and configure a low-stock threshold for a product.
FR-04	The system shall identify products at or below their configured low-stock threshold.
FR-05	The system shall allow a user to create and update orders with customer, product, quantity, delivery, discount, and status information where applicable.
FR-06	The system shall support the order statuses New, Confirmed, Processing, Shipped, and Delivered, and shall display the current status for each order.
FR-07	The system shall maintain customer profiles and show the orders and purchase totals linked to each profile.
FR-08	The system shall calculate sales summaries for a selected time period from recorded orders.
FR-09	The system shall calculate estimated profit using recorded revenue, product cost, delivery cost, discount, and other entered expenses, and identify any excluded or missing cost values.
FR-10	The system shall display product and sales summaries through readable tables or charts.
FR-11	The system shall provide an internal inbox interface where a user can enter a customer message and request a reply suggestion.
FR-12	The system shall allow the user to edit or discard an AI-generated reply suggestion; the system shall not send it automatically.
FR-13	The system shall allow a user to request a business summary for a selected store or time period and display the data period used.
FR-14	The system shall classify customers into defined behavioral segments using available purchase data and display the rule or criteria for each segment.
FR-15	The system shall allow a user to request a product-demand estimate for a selected future period when sufficient historical data is available.
FR-16	When historical data is insufficient for a forecast, the system shall state that a reliable forecast cannot be generated and may display descriptive historical sales instead.
FR-17	The system shall allow a user to configure a supported price or discount scenario for a selected product.
FR-18	The system shall display what-if results as estimates, including the assumptions or input values used.

ID	Requirement
FR-19	The system shall keep a record of the inputs used for an AI request sufficiently to support debugging and evaluation, while following the project's data-retention and privacy decisions.
FR-20	The system shall distinguish AI-generated text from verified product, inventory, and calculated business values.

AI Requirements

ID	Requirement
AIR-01	For a customer-reply request, the system shall retrieve relevant product, variant, price, and stock information from the current store before generating a suggestion.
AIR-02	The system shall not present a product availability or price claim as verified unless that value is present in the retrieved store data.
AIR-03	The system shall generate a business insight summary from computed metrics and records for the selected time period and identify the period or metrics used.
AIR-04	The system shall assign customer segments using the approved purchase-behavior features and shall not use sensitive personal attributes for segmentation.
AIR-05	For each demand forecast, the system shall identify the product and forecast horizon and provide a numerical estimate only when the selected method's minimum data conditions are met.
AIR-06	The team shall evaluate the forecast against a simple baseline using a documented time-aware validation method when sufficient historical data is available.
AIR-07	Profit values shall be computed from explicit recorded fields; an LLM may explain but shall not be the source of arithmetic results.
AIR-08	The system shall label scenario results as estimates and expose the selected change and material assumptions.
AIR-09	When relevant input data is missing, inconsistent, or too limited, the system shall disclose the limitation or request additional data rather than invent a specific business fact.
AIR-10	A user shall review AI-generated customer text and scenario outputs before taking an external action.

Non-Functional Requirements

ID	Requirement
NFR-01 Security	The system shall require authenticated access to seller data and shall enforce store-level access checks on protected application requests.

ID	Requirement
NFR-02 Privacy	The system shall collect only information needed for the prototype, restrict access to customer records, and document how test data is stored and removed.
NFR-03 Usability	A first-time user shall be able to complete core product and order tasks using clearly labeled forms and receive validation messages for invalid required fields.
NFR-04 Performance	For the agreed capstone test dataset and deployment environment, the team shall measure and report the response time of core record and analytics requests; no unverified response-time target is assumed at proposal stage.
NFR-05 Reliability	The system shall validate required input and return a clear error message when a request fails, without silently saving incomplete or inconsistent business records.
NFR-06 Explainability	Forecasts, profit figures, segments, and scenario outputs shall identify their relevant period, inputs, formula, or criteria in a form suitable for user review.
NFR-07 Maintainability	The application shall separate frontend, backend API, persistence, and AI/ML responsibilities so that each component can be changed and tested independently.
NFR-08 Scalability	The database and API design shall use normalized store-related records and pagination or filtering for lists where appropriate; performance under larger workloads will be considered future evaluation.
NFR-09 Availability	The prototype's deployment environment and any service limitations shall be documented for the demonstration; uninterrupted production availability is outside the capstone guarantee.
NFR-10 Responsible AI	AI text shall be presented as a suggestion, and numerical outputs shall be calculated or model-generated with disclosed limitations rather than described as guaranteed outcomes.

3. Tools and Technologies

The proposed stack follows the current project draft. The final selection may be adjusted if implementation constraints require it, but any change should preserve the separation between the user interface, application API, database, and AI/ML logic.

Layer	Planned technology	Purpose
Frontend	React, Vite, TypeScript	Build the interactive web interface and type-check client-side code; Vite supports the frontend development and build workflow.
UI and data display	Tailwind CSS, shadcn/ui, TanStack Query, Recharts	Create consistent responsive components, manage API data fetching/caching, and display sales and business summaries.
Backend	Python, Django, Django REST Framework, Django ORM	Implement business rules, authentication and API endpoints, validation, and database access.

Layer	Planned technology	Purpose
Database	PostgreSQL or SQL	Store seller, product, inventory, order, customer, and expense records in a relational database.
Data analysis / ML	Python, Pandas, NumPy, Scikit-learn; XGBoost where appropriate	Prepare and analyze structured business data, establish baselines, and implement suitable forecasting or segmentation approaches.
LLM integration	LLM API	Draft context-grounded customer replies and explain computed business summaries. API use will be isolated in the backend, with credentials kept out of browser code.

An external LLM API introduces dependency, cost, and privacy considerations. The team should choose a provider based on availability, terms, cost, and data-handling requirements before implementation. This proposal does not assume a specific provider or that customer messages may be sent to any service without review. A local or rule-based fallback may be used for demonstration if an API is unavailable.

4. Project Timeline and Work Plan

The initial planning, requirements understanding, architecture, technology selection, project setup, and proposal preparation have been completed or substantially progressed during the first month of the four-month capstone. The remaining work is planned across 11 weeks. Tasks overlap where dependencies allow; testing and evaluation begin during development and continue through integration.

Remaining week / milestone	Main activities	Monira Islam Member 1	Rukaiya Akther Trisha Member 2	Expected deliverable
Week 1 Foundation	Finalize the working schema and API contract; prepare authorized/sample data and validation rules; establish frontend and backend branches/modules.	Implement PostgreSQL/Django models and initial authentication/API structure; confirm data constraints.	Set up React application shell, navigation and form patterns; map core user workflows and prepare data-quality/test cases.	Agreed schema/API contract, runnable application skeleton, and prepared test-data plan.
Week 2 Core records	Build product, inventory, customer, and order workflows in parallel; connect core screens to APIs.	Complete CRUD endpoints, validation, relationships, and inventory/order business rules.	Implement product, inventory, customer, and order screens; connect API calls and verify field validation.	Connected operational workflows with representative records.
Week 3 Integration and analytics base	Integrate core modules; add sales summaries and dashboard foundation; continue functional checks.	Implement sales aggregation and reliable API responses; resolve integration defects.	Build dashboard layout, tables/charts, and filters; verify displayed totals against test records.	Integrated MVP data flow and verified baseline analytics.
Week 4 AI Customer Assistant	Implement customer message → store-record retrieval → LLM draft → seller review flow.	Build backend retrieval and prompt/context handling; keep provider credentials server-side; add safe fallback/error handling.	Build inbox and review/edit UI; connect response endpoint; create test prompts and assess relevance and factual grounding with the team.	Working reply-suggestion flow with review controls and documented test cases.

Remaining week / milestone	Main activities	Monira Islam Member 1	Rukaiya Akther Trisha Member 2	Expected deliverable
Week 5 AI Business Advisor and Profit Intelligence base	Add computed business metrics and AI explanations; implement deterministic profit calculations.	Implement explicit revenue/cost/discount/expense formulas and summary API; prepare grounded context for explanations.	Build period selection, metric cards/charts, and insight display; compare shown metrics to source records and assess explanation usefulness jointly.	Business summaries and auditable estimated-profit metrics with clear inputs.
Week 6 Customer Segmentation	Prepare customer features and implement interpretable behavioral groups; expose criteria and results in the UI.	Implement approved recency/frequency/spending features and rule-based baseline; evaluate clustering only if suitable.	Create segment views, filters, and criteria explanations; prepare representative customer cases and jointly review consistency and interpretability.	Visible, documented customer segments based on non-sensitive behavior features.
Week 7 Demand Forecasting	Prepare time-ordered sales data and implement/evaluate a suitable forecast against a simple baseline.	Build data pipeline, forecast method and baseline comparison with time-aware validation when history permits.	Build forecast selection/results visualization and disclose horizon, data period, and limitations; prepare validation cases and review outputs jointly.	Forecast prototype or transparent insufficient-data response, with evaluation record.
Week 8 Profit Intelligence and scenario foundation	Complete profitability views and implement transparent price/discount scenario inputs and calculations.	Verify deterministic profitability formulas and scenario calculation service; document assumptions and missing-cost behavior.	Build profitability breakdown and scenario input/result UI; check scenario outputs against hand-calculated cases with the team.	Auditable profit and scenario foundation with visible assumptions.
Week 9 What-if Simulator and AI feature integration	Complete user-defined scenarios; integrate six feature flows with dashboards and core records.	Connect backend services, model/LLM calls, validation, and scenario endpoints; fix cross-module defects.	Integrate assistant, advisor, segments, forecasts, profit, and simulator interfaces; test end-to-end journeys and collect evaluation notes.	Integrated six-feature prototype and end-to-end test cases.
Week 10 System validation and refinement	Run functional, AI-feature, performance, and usability validation; prioritize and fix defects.	Run API/security/data-integrity and forecast/scenario consistency checks; resolve backend and integration defects.	Lead structured workflow/usability scenarios and output presentation checks; jointly assess reply grounding, insight consistency, segment interpretability, and record results.	Test and AI-feature evaluation summary, defect log, and refined prototype.
Week 11 Release and presentation preparation	Complete final integration, deployment/demo rehearsal, documentation, and presentation/viva preparation.	Stabilize deployment/API configuration; document architecture, data flow, formulas, AI methods, limitations, and technical setup.	Polish user flows and visualizations; complete user guide, test/evaluation summary, and presentation materials; rehearse module demonstrations jointly.	Demonstration-ready prototype, final documentation, and coordinated presentation.

5. Optional Sections

5.1 Ethical, Legal, and Social Considerations

SellerOS may contain customer names, contact details, order histories, messages, and transaction-related information. The prototype should use only information necessary to demonstrate the project. The team should prefer synthetic or anonymized evaluation data unless it has permission to use real data, limit access to authorized users, avoid placing secrets in frontend code, and document retention and deletion practices. Applicable institutional and local requirements should be confirmed before any real customer data is collected or processed.

AI-generated replies may state an incorrect price, variant, or availability if the context is incomplete or misunderstood. The assistant will therefore retrieve current store records, mark its output as a suggestion, and require seller review before sending. Forecasts and scenarios may be misleading when order history is sparse, incomplete, seasonal, or affected by events not represented in the data. The interface should disclose the input period and limitations and should not imply a guaranteed outcome.

Customer segments can influence how a seller treats different customers. SellerOS will use business-behavior features such as order recency, order frequency, and spending, and will avoid sensitive traits. Segment definitions should be visible and adjustable where appropriate. The project should not use segments to deny service or make high-impact decisions. The team should review LLM-provider terms and data controls before transmitting any messages or business records to an external API.

5.2 Future Work

After the standalone prototype has been evaluated, future versions may consider live integrations with Facebook Messenger, Instagram, or WhatsApp Business; courier and payment services; automated follow-up workflows; and multi-store support. These extensions would require separate review of platform permissions, API availability, data protection, and operational reliability. Further work could also evaluate forecasting on a larger authorized dataset, compare additional methods, improve uncertainty communication, and test usability with social-commerce sellers. These are possible extensions and are not promised as current capstone deliverables.
